

Title	Stringency of start codon selection modulates autoregulation of translation initiation factor eIF5
Authors	Loughran, Gary;Sachs, Matthew S.;Atkins, John F.;Ivanov, Ivaylo P.
Publication date	2012
Original Citation	Loughran, G., Sachs, M. S., Atkins, J. F. and Ivanov, I. P. (2012) 'Stringency of start codon selection modulates autoregulation of translation initiation factor eIF5', Nucleic Acids Research, 40(7), pp. 2898-2906. doi: 10.1093/nar/gkr1192

Supplementary Data

Supplementary Figure S1. Nucleotide sequences used for generating logograms.

Alignments of the 10 nucleotides surrounding the uAUG start codons of eIF5 that define their initiation contexts are shown for: (A) vertebrates; (B) arthropods; (C) nematodes; (D) molluscs; (E) Pezyzomycotina; (F) Basidiomycota; (G) fungi other than Pezyzomycotina or Basidiomycota; (H) plants. Species names are on the right. Species names in quotation marks specify presumed contaminant sequences that cluster with eIF5 sequences from an unrelated taxonomic group. Some plants have more than one paralog of eIF5. Here they are arbitrarily labelled “#1”, “#2”, “#3” or “#4” and their placement in one of the groups does not imply orthologous clusters. For each species the sequence on top is the context of the first uAUG and subsequent uAUG contexts are shown in descending order. The initiation codon is highlighted in green. Nucleotides in positions -3 and +4 are highlighted in red if they deviate from the Kozak consensus and in gray if they comply with it. Species names in quotation marks represent sequences derived from Expressed Sequence Tags that by similarity analysis of the main open reading frame do not match eIF5 homologs from the phylum to which the species belongs and instead likely belong to contaminating sequences of unknown species. These sequences are grouped with the taxonomic group to which they actually belong determined by reconstructed phylogenetic trees with the entire sequence.

Supplementary Figure S2. Weblogo representation of amino acid conservation in eIF5 uORF1 encoded peptides.

Letter heights are proportional to the frequency of conservation of each amino acid at each position. Each line represents a different eukaryotic branch which is indicated in parentheses on the right followed by the number of sequences used in each alignment. The sequences used to generate the alignment presented in this figure are available upon request.

Supplementary Figure S2

[illegible]

Supplementary Figure S3. Removing eIF5 uORFs results in constitutive eIF5 expression.

(A) Western blots of protein lysates from cells transfected in triplicate with the eIF5 or eIF1 overexpression constructs indicated in Figure 2B of the main text. The eIF1 overexpression construct is the “eIF1 good*” described previously (2). In lanes marked “10×”, 10-fold more vector with insert was transfected compared with lanes marked “1×,” where the difference in the amount of transfecting DNA is made up with the inert vector pcDNA3 (2). The control cells are transfected with “10×” amount of pcDNA3. The blot shown was probed with anti-eIF5 and anti-β-actin followed by anti-eIF1. The corresponding detected proteins are indicated by arrows. (B & C) Densitometry analysis of the western blot shown in A. Relative eIF5 levels (B) and eIF1 levels (C) were determined by normalizing to β-actin levels.
